Basic Equations

Atoms to Moles

A mole is an SI unit for measuring an amount of substance. The number of moles of anything can be calculated by taking the number of particles, (atoms, things, etc.) and dividing it by Avogadro's number.

Avogadro's Number

$$6.022 \times 10^{23}$$

$$\# \text{ Moles} = (\# \text{ Particles}) \times \frac{1 \text{ mole}}{6.02 \times 10^{23} \text{ particles}}$$

Fahrenheit to Celsius

Most chemistry equations use temperature in degrees C or Kelvins. If given temperature in F, you can convert to C with the following equation.

$$^{\circ}\text{C} = (^{\circ}\text{F} - 32) \times \frac{5}{9}$$

Ex.

$$50^{\circ}\text{F} = (50 - 32) \times \frac{5}{9} = 10^{\circ}\text{C}$$

Celsius to Fahrenheit

If given temperature in C, you can convert to F with the following equation.

$$^{\circ}\text{F} = \left(^{\circ}\text{C} \times \frac{9}{5}\right) + 32$$

Ex.

$$10^{\circ}\text{C} = 10 \times \frac{9}{5} + 32 = 50^{\circ}\text{F}$$

Celsius to Kelvins

If given temperature in C, you can convert to K with the following equation.

$$K = ^{\circ}\text{C} + 273.15$$

Ex.

$$50^{\circ}\text{C} = 50 + 273.15 = 323.15\text{K}$$

Solutions

Molarity

$$\frac{\text{moles}_{\text{solute}}}{L_{\text{solution}}}$$

Molarity is a measure of solution concentration which is calculated as the moles of solute per liter of solution.

Molality

$$\frac{\text{moles}_{\text{solute}}}{\text{kg}_{\text{solvent}}}$$

Molality is a measure of solution concentration which is calculated as the moles of solute per kilogram of solvent.

pH & pOH

$$pH = -\log[H^+]$$

$$pOH = -\log[OH^-]$$

pH specifies the acidity or basicity of a solution, where $[H^+]$ means the concentration of hydrogen ions and $[OH^-]$ is the concentration of hydroxide ions.

Henderson-Hasselbalch Acid Dissociation

$$pH = pK_a + \frac{[A^-]}{[HA]} = pK_a + \frac{[Base]}{[Acid]}$$

Relationship between pH and pKa

Atomic Structure

DeBroglie

$$\lambda = \frac{h}{mv}$$

Particles can behave like waves. A wavelength can be given to a particle if the mass m and velocity v is known. h is Planck's constant.

Planck Einstein Relation

$$E = hf = \frac{hc}{\lambda}$$
$$c = \lambda f$$

Where h is Planck's constant

Gases

Boyle's Law

$$P_1 V_1 = P_2 V_2$$

Used when temperature is constant. P_1 and V_1 are the initial pressure and volume, and P_2 and V_2 are the new volume and pressure.

Charles' Law

$$\frac{V_1}{T_1} = \frac{V_2}{T_2}$$

Used when pressure is constant. V_1 and T_1 are the initial volume and temperature, and T_2 and V_2 are the new temperature and pressure.

Ideal Gas

$$PV = nRT$$

Where R is the ideal gas constant

Thermodynamics

Heat Energy

$$Q = mC\Delta T$$

Where m is mass of a substance (kg), c is the specific heat (J/kg·K), and ΔT is change in temperature (Kelvins, K or Celsius, C)

Ex. A glass of water loses heat to the environment
